- Power Divider Design Aspect
- Circulator

Power Dividers and Couplers

• One of the most fundamental problems in RF/microwave engineering is how to efficiently **divide** signal power.

 The simplest RF/microwave problem would seemingly be to equally divide signal power in two.

However, building these devices is **more difficult** than you might think!

Basic Properties of Couplers and Dividers

First let's examine four-port networks called directional couplers, and explain some fundamental values that characterize them

Directional Coupler

- A directional coupler is a 4-port network that is designed to divide and distribute power.
- Although this would seem to be a particularly mundane and simple task, these devices are both very important in high frequency systems, and at the same time very difficult to design and construct.
- Two of the **reasons** for this difficulty are our desire for the device to be:
 - 1. Matched
 - 2. Lossless

Thus, we require a **matched**, **lossless**, and (to make it simple) **reciprocal** 4-port device!

Recall that a matched, lossless, reciprocal, 4-port device was difficult to even **mathematically** determine, as the resulting scattering matrix must be (among other things) **unitary**.

• However, we were able to determine two possible mathematical solutions, which we called the **symmetric** and **asymmetric** solutions respectively:

- For both cases, the relationship $|\alpha|^2 + |\beta|^2 = 1$ must be true in order for the device to be lossless (i.e, for **S** to be unitary)
- For most couplers it can be found that α and β can (at least ideally) be represented by a real value c, known as the coupling coefficient.

$$\beta = c \qquad \qquad \alpha = \sqrt{1 - c^2}$$

ECE321/521

Directional Coupler (contd.)

• The symmetric solution is thus described as:

• And the **asymmetric** solution is described as:

$$S = \begin{bmatrix} 0 & \sqrt{1-c^2} & c & 0 \\ \sqrt{1-c^2} & 0 & 0 & -c \\ c & 0 & 0 & \sqrt{1-c^2} \\ 0 & -c & \sqrt{1-c^2} & 0 \end{bmatrix}$$

• Additionally, for a directional coupler, the coupling coefficient c will be **always** less than $\frac{1}{\sqrt{2}}$. Therefore, we can express:

$$0 \le c \le \frac{1}{\sqrt{2}} \qquad \qquad \frac{1}{\sqrt{2}} \le \sqrt{1 - c^2} \le 1$$

- Let's see what this means in terms of the physical behavior of a directional coupler.
- First, consider the case where some signal is incident on **port 1**, with power P₁⁺.
- If all other ports are matched, the power $P_1^- = |S_{11}|$ flowing out of **port 1** is:
- While the power out of **port 2** is:
- and the power out of **port 3** is:
- Finally, we find there is **no power** flowing out of $P_4^- = |S_{41}|^2$ **port 4**:

$$P_1^- = \left| S_{11} \right|^2 P_1^+ = 0^2 * P_1^+ = 0$$

$$P_2^- = \left|S_{21}\right|^2 P_1^+ = (1 - c^2)P_1^+$$

$$P_3^- = |S_{31}|^2 P_1^+ = c^2 P_1^+$$

$$P_4^- = \left| S_{41} \right|^2 P_1^+ = 0^2 * P_1^+ = 0$$

In the terminology of the directional coupler, we say that port 1 is the input port, port 2 is the through port, port 3 is the coupled port, and port 4 is the isolation port

Note however, that **any** of the coupler ports can be an input, with a **different** through, coupled and isolation port for each case

• For example, **if** a signal is incident on **port 2**, while all other ports are matched, we find that:

 Thus, from the scattering matrix of a directional coupler, we can form the following table:

Input	Through	Coupled	Isolation
Port 1	Port 2	Port 3	Port 4
Port 2	Port 1	Port 4	Port 3
Port 3	Port 4	Port 1	Port 2
Port 4	Port 3	Port 2	Port 1

• **Typically**, the coupling coefficients for a directional coupler are in the range of approximately:

 $0.25 > c^2 > 0.0001$

 $-c^2 \approx 1$

• As a result, we find that:

What this means is that the power out of the **through** port is just **slightly smaller** (typically) than the power incident on the input port

Similarly, the power out of the **coupling** port is typically a **small fraction** of the power incident on the input port

A: A directional coupler is often used for **sampling** a small portion of the signal power. For example, we might **measure** the output power of the **coupled** port (e.g., P_3^-) and then we can determine the amount of signal power flowing through the device (e.g., $P_1^+ = P_3^-/c^2$).

Unfortunately, the **ideal** directional coupler **cannot** be built! For example, the input match is never **perfect**, so that the diagonal elements of the scattering matrix, although **very small**, are not zero.

Similarly, the isolation port is never **perfectly** isolated, so that the values S_{41} , S_{32} , S_{23} and S_{14} are also non-zero—some **small** amount of power leaks out!

As a result, the through port will be **slightly less** than the value $\sqrt{1-c^2}$. The scattering matrix for a **non-ideal coupler** would therefore look like as: $S = \begin{bmatrix} S_{11} & S_{21} & jc & S_{41} \\ S_{21} & S_{11} & S_{41} & jc \\ jc & S_{41} & S_{11} & S_{21} \\ S_{41} & jc & S_{21} & S_{11} \end{bmatrix}$

From **this** scattering matrix, we can extract **some important parameters** about directional couplers

Coupling Coefficient, C

The **coupling coefficient** is the ratio of the coupled output power (P_3^-) to the input power (P_1^+) , expressed in decibels as:

$$C(dB) = 10\log_{10}\left[\frac{P_3^-}{P_1^+}\right] = -10\log_{10}\left|jc\right|^2$$

This is the **primary** specification of a directional coupler!

- Note the **larger** the coupling value, the **smaller** the coupled power! For example:
 - A 6 dB coupler couples out 25% of the input power
 - A **10 dB** coupler couples out **10%** of the input power
 - A **20 dB** coupler couples out **1.0%** of the input power
 - A **30 dB** coupler couples out **0.1%** of the input power

Directivity, D

The **directivity** is the ratio of the power **out** of the coupling port (P_3^-) to the power **out** of the isolation port (P_4^-), expressed in decibels.

$$D(dB) = 10\log_{10}\left[\frac{P_3^-}{P_4^-}\right] = 10\log_{10}\left[\frac{|jc|^2}{|S_{41}|^2}\right]$$

This value indicates how effective the device is in "directing" the coupled energy into the correct port (i.e., into the coupled port, **not** the isolation port)

Ideally this is infinite (i.e., $P_4^-=0$), so the **higher** the directivity, the **better**

Isolation, I

Isolation is the ratio of the **input power** (P_1^+) to the power out of the **isolation** port (P_4^-) , expressed in decibels.

$$I(dB) = 10\log_{10}\left[\frac{P_1^+}{P_4^-}\right] = -10\log_{10}\left[\left|S_{41}\right|^2\right]$$

This value indicates how "isolated" the isolation port actually is. **Ideally** this is infinite (i.e., $P_4^- = 0$), so the **higher** the isolation, the better

Note that isolation, directivity, and coupling are not independent values!
 You should be able to quickly show that:

I(dB) = C(dB) + D(dB)

 $ML(dB) = 10\log_{10} \left| \frac{P_1^+}{P_2^-} \right| = -10\log_{10} \left[\left| S_{21} \right|^2 \right]$

Mainline Loss, ML

The **mainline loss** is the ratio of the **input** power (P_1^+) to the power out of the **through** port (P_2^-) , expressed in decibels.

It indicates how much power the signal **loses** as it travels from the input to the through port

Coupling Loss, CL

The **coupling loss** indicates the **portion** of the mainline loss that is due to coupling some of the input power into the coupling port.

$$CL(dB) = 10\log_{10}\left[\frac{P_1^+}{P_1^+ - P_3^-}\right] = -10\log_{10}\left[1 - |jc|^2\right]$$

Indraprastha Institute of Information Technology Delhi

ECE321/521

Directional Coupler (contd.)

$$CL(dB) = 10\log_{10}\left[\frac{P_1^+}{P_1^+ - P_3^-}\right] = -10\log_{10}\left[1 - |jc|^2\right]$$

Conservation of energy conveys that this loss is **unavoidable**

- Note this value can be **very small**, for example:
 - The coupling loss of a **10dB** coupler is **0.44 dB**
 - The coupling loss of a **20dB** coupler is **0.044 dB**
 - The coupling loss of a **30dB** coupler is **0.0044 dB**

Insertion Loss, IL

Q: But wait, shouldn't $(P_1^+ - P_3^-) = P_2^-$, meaning the coupling loss and the mainline loss will be the **same exact value**?

- A: Ideally this would be true.
- But, the reality is that couplers are not perfectly lossless, so there will additionally be loss due to absorbed energy (i.e., heat). This loss is called insertion loss and is simply the difference between the mainline loss and coupling loss:

$$IL(dB) = ML(dB) - CL(dB)$$

The insertion loss thus indication loss that is **not** due to coupling port. This insertion

The insertion loss thus indicates the portion of the mainline loss that is **not** due to coupling some input power to the coupling port. This insertion loss **is** avoidable, and thus the **smaller** the insertion loss, the better.

For couplers with very small coupling coefficients (e.g., C(dB) > 20) the coupling loss is so small that the mainline loss is almost entirely due to insertion loss (i.e., ML = IL) → often then, the two terms are used interchangeably.

The T – Junction Power Divider

- Three-port couplers are also known as T Junction Couplers, or T Junction Dividers.
- Let us say that we desire a **matched** and **lossless** 3-port coupler.

Absolutely true! Our desire in this case will be **unfulfilled**. There are, however, a few designs that come **close**.

The T – Junction Power Divider (contd.)

- The Lossless Divider As the name states, this divider is lossless. It is likewise reciprocal, and thus is not matched.
- The Resistive Divider As the name implies, this divider is lossy. However, it is both matched and reciprocal.
- The Circulator This three-port divider is both matched and (ideally) lossy. This of course means that it is not reciprocal!
- **4.** The Wilkinson Divider Like the resistive divider, it is matched and reciprocal, and thus is lossy. However, it is lossy in a way that is not apparent when power is divided (i.e., power can be divided without loss).

As a result, the Wilkinson Power Divider is in most ways as **ideal** a T-junction as there is. Accordingly, it has its very **own importance** in RF/microwave applications !

The Resistive Divider

• Let us consider the following **resistive power divider**:

ECE321/521

The Resistive Divider (contd.)

- From the symmetry of the circuit, we find that all the other ports will be matched as well (i.e., S₁₁ = S₂₂ = S₃₃ = 0).
- Furthermore, it can be shown that:

$$S_{12} = S_{21} = S_{13} = S_{31} = S_{23} = S_{32} = \frac{1}{2}$$

• Note the magnitude of each column is less than one. e.g.:

 $|S_{21}|^2 + |S_{31}|^2 = \frac{1}{2} < 1$ Therefore this power divider is **lossy**!

In fact, we find that the power out of each port is just one quarter of the input power:

$$P_2^- = P_3^- = \left(P_1^+ / 4\right)$$

In other words, **half** the input power is **absorbed** by the divider!

The Lossless Divider

• Now let us consider the following **lossless power divider**:

The Lossless Divider (contd.)

• As the divider is **lossless** (no resistive components), we can write:

$$P_1^+ = P_2^- + P_3^-$$

where P_1^+ is the power incident (and absorbed if $S_{11}^- = 0$) on port 1, and P_2^- and P_3^- is the power absorbed by the matched loads of ports 2 and 3.

• Unless $Z_{02} = Z_{03}$, the power will not divide equally between P_2^- and P_3^- . With a little high frequency circuit analysis, it can be shown that the **division ratio** k is:

$$k = \frac{P_2^-}{P_3^-} = \frac{Z_{03}}{Z_{02}}$$

Thus, if we desire an ideal (S₁₁ = 0) divider with a specific division ratio k, we will find that:

Indraprastha Institute of Information Technology Delhi

The Lossless Divider (contd.)

Q: I don't understand how this is helpful. Don't we typically want the characteristic impedance of all three ports to be equal to the **same** value (e.g., $Z_{01} = Z_{02} = Z_{03} = Z_0$)?

A: True ! A more practical way to implement this divider is to use a **matching network**, such as a quarter wave transformer, on ports 2 and 3:

The Lossless Divider (contd.)

- Where the (non-zero!) values of S₂₂, S₂₃, S₃₂, and S₃₃ depend on the division ratio k.
- Note that if we desire a **3 dB** divider (i.e., **k** = 1), then:

$$Z_{02} = Z_{03} = 2Z_{01}$$

• This **3dB** lossless divider (where $Z_{02} = Z_{03} = 2Z_{01}$), would have this design:

Circulators

 Circulator is a matched, lossless but non-reciprocal 3-port device, whose scattering matrix is ideally:

- Circulators use anisotropic ferrite materials, which are often "biased" by a permanent magnet!
 The result is a nonreciprocal device!
- First, we note that for a circulator, the power incident on port 1 will exit completely from port 2:

$$P_2^- = P_1^+$$

Indraprastha Institute of Information Technology Delhi

ECE321/521

Circulators (contd.)

Pardon me while I feign **ignorance. This unremarkable** behavior is likewise true for the simple circuit below, which requires just a length of **transmission line. Oh please, continue**

to waste our valuable time.

 True! But a transmission line, being a reciprocal device, will likewise result in the power incident on port 2 of your simple circuit to exit completely from port 1 (P₁⁻=P₂⁺):

But, this is **not true for a circulator! If power is incident on** port 2, then **no power will exit port 1 !**

Likewise, power flowing into port 3 will exit—port 1!

It is evident, then how the circulator gets its **name: power** appears to **circulate around the device, a behavior that is** emphasized by its device **symbol**

We can see that, for example, a **source at port 2 "thinks" it is** attached to a **load at port 3, while a load at port 2 "thinks" it is** attached to a **source at port 1!**

 These type of behavior is useful, for example, when we want to use one antenna as both the transmitter and receiver antenna. The transmit antenna (i.e., the load) at port 2 gets its power from the transmitter at port 1. However, the receive antenna (i.e., the source) at port 2 delivers its power to the receiver at port 3!

It is **particularly important to keep the transmitter power from** getting to the receiver. To accomplish this, the **antenna must** be **matched to the transmission line. Do you see why?**

- It is important that we should note some major **drawbacks of a circulator**:
 - 1. They're expensive.
 - 2. They're heavy.
 - **3.** The generally produce a large, static magnetic field.

4. They typically exhibit a large insertion loss (e.g., $|S_{21}|^2 = |S_{32}|^2 = |S_{13}|^2 \approx 0.75$).

The (Nearly) Ideal T- Junction Power Divider

- Recall that we cannot build a matched, lossless reciprocal three-port device.
- So, let's **mathematically try and determine the scattering** matrix of the best possible T-junction 3 dB **power divider.**

- To efficiently divide the power incident on the input port, the port (port 1) must first be matched (i.e., all incident power should be delivered to port 1): $S_{11} = 0$
- Likewise, this delivered power to port 1 must be divided efficiently (i.e., without loss) between ports 2 and 3.
- Mathematically, this means that the first column of the scattering matrix must have magnitude of 1.0:

$$|S_{11}|^2 + |S_{21}|^2 + |S_{31}|^2 = 1$$

The (Nearly) Ideal T- Junction Power Divider (contd.)

Provided that we wish to evenly divide the input power, we can conclude from the expression above that:

Note that this device would take the power into port 1 and divide into two equal parts—half exiting port 2, and half exiting port3 (provided ports 2 and 3 are terminated in matched loads!).

$$P_2^- = |S_{21}|^2 P_1^+ = 0.5P_1^+$$
 $P_3^- = |S_{31}|^2 P_1^+ = 0.5P_1^+$

In addition, it is desirable that ports 2 and 3 be matched (the whole device is thus matched):

And also desirable that ports 2 and 3 be isolated:

 $S_{23} = S_{32} = 0$

This last requirement ensures that no signal incident on port 2 (e.g., reflected from a load) will "leak" into port 3—and vice versa.

The (Nearly) Ideal T- Junction Power Divider (contd.)

• The ideal 3 dB power divider **could therefore have the form**:

Since we can describe this ideal power divider mathematically, we can potentially build it physically!

Q: Huh!? I thought you said that a matched, lossless, reciprocal three-port device is impossible?

A: It is! This divider is clearly a lossy device. The magnitudes of both column 2 and 3 are less than one:

$$|S_{12}|^{2} + |S_{22}|^{2} + |S_{32}|^{2} = \left|-j/\sqrt{2}\right|^{2} + 0 + 0 = 0.5 < 1$$
$$|S_{13}|^{2} + |S_{23}|^{2} + |S_{33}|^{2} = \left|-j/\sqrt{2}\right|^{2} + 0 + 0 = 0.5 < 1$$

Indraprastha Institute of Information Technology Delhi

The (Nearly) Ideal T- Junction Power Divider (contd.)

Note then that **half the power incident on port 2 (or port 3)** of this device would **exit port 1 (i.e., reciprocity), but no power** would exit port 3 (port2), since ports 2 and 3 are **isolated. i.e.,**

$$P_{1}^{-} = |S_{12}|^{2} P_{2}^{+} = 0.5P_{2}^{+} \qquad P_{3}^{-} = |S_{32}|^{2} P_{2}^{+} = 0 * P_{2}^{+} = 0$$
$$P_{1}^{-} = |S_{13}|^{2} P_{3}^{+} = 0.5P_{3}^{+} \qquad P_{2}^{-} = |S_{23}|^{2} P_{3}^{+} = 0 * P_{3}^{+} = 0$$

Q: Any ideas on how to build this thing?

A: Note that the first column of the scattering matrix is precisely the same as that of the lossless 3 dB divider.

Also note that since the device is **lossy, the design must** include some **resistors.**

Lossless Divider + resistors = The Wilkinson Power Divider

Topic of our next lecture!
